

The problem that I will be attempting to solve is one of time management, currently many students struggle with time management and managing both academics and extracurriculars with many having to use a variety of disconnected apps to do so. For my project I plan to create an all in one calendar with intelligent and automatic scheduling for tasks that don't have specific dates, such as studying, and normal and frequent reminders for tasks that do have, such as deadlines.

Success criteria:

- Implementation of an auto-selection algorithm
- Creation of GUI
- Proper colours for all tasks
- Description boxes for all tasks
- Make sure it can detect scheduling conflicts
- Make sure each task can have a date, and time written to it and is shown clearly
- Store data properly even when closed
- Filters for things such as recency, and importance
- Task grouping
- Store user information into an account
- Create reminders hours/days before each task that appear on screen/as a notification

The computational context for this project would firstly be found in algorithm design as this project heavily relies on the exploitation of one that works properly. I would also need good data management in order to create accounts and store tasks. Finally I would need good OOP and UI in order to be able to show all of the information visually and clearly.
